Number of households and average household size in Florida: April 1, 1985

by Stanley K. Smith
Population Program Director
Bureau of Economic and Business Research
University of Florida

This publication shows the number of households and average household size for Florida and each of its counties for 1970, 1980 and 1985. Households are defined as housing units occupied by permanent residents. They should not be confused with total housing units, which include vacant and seasonally occupied units as well as units occupied by permanent residents. According to the United States Bureau of the Census, a person is classified as a permanent resident of "...his usual place of residence, which is generally construed to mean the place where he lives and sleeps most of the time. This place is not necessarily the same as his legal residence, voting residence or domicile." The numbers shown in this bulletin refer only to the number of households and average household size of permanent Florida residents.

Data for 1970 and 1980 were taken from actual census counts conducted by the United States Bureau of the Census. Data for 1985 were taken from estimates produced by the Bureau of Economic and Business Research. Estimates of households were based on electric customer and building permit data (primarily the former). Estimates of average household size were based on each area's average household size in 1980, the national decline in average household size since 1980 and the local change in housing mix since 1980. A more detailed description of the methodology used to estimate households and average household size can be found in "Some New Techniques for Applying the Housing Unit Method of Local Population Estimation," *Demography*, Volume 17, Number 3, August, 1980.

Number of households

There were 4,444,889 permanent households in Florida on April 1, 1985, an increase of 700,635 (or 18.7 percent) since 1980. Dade County had by far the most households of any county in Florida in 1985, with 658,622. Other top counties in 1985 were Broward (472,689), Pinellas (359,956), Palm Beach (298,054), Hillsborough (286,880), Duval (231,630) and Orange (208,033). The counties with the smallest number of households in 1985 were Lafayette (1,557), Liberty (1,629), Gilchrist (2,315), Union (2,488) and Glades (2,665).

Palm Beach had the largest numerical increase in households between 1980 and 1985, growing by 63,715. Other large increases occurred in Broward (55,172), Hillsborough (48,937), Dade (48,792), Pinellas (40,429) and Orange (37,279). In terms of percentage growth rates, the most rapid increases were found in Osceola (61.5 percent), Hernando (56.3 percent) and Flagler (51.2 percent). No county in Florida lost households between 1980 and 1985, but the increase was less than 400 in Calhoun, Franklin, Gilchrist, Gulf, Hamilton, Jefferson, Lafayette, Liberty, Union and Washington counties.

Average household size

Average household size in Florida fell from 2.90 in 1970 to 2.55 in 1980, a decline of 12.1 percent. This decline was

caused by falling birth rates, increasing divorce rates, the large number of older persons moving into the state and the growing tendency for single persons to live alone. Since 1980 the trend toward smaller average household size has continued, but at a less rapid pace. We estimate that average household size in Florida fell only 2.7 percent between 1980 and 1985, from 2.55 to 2.48. Birth rates have increased somewhat since 1980, and the heavy influx of Cuban and Haitian immigrants has also been a factor, as many immigrants have moved in with friends or relatives, rather than setting up their own households. We estimate that average household size declined between 1980 and 1985 in every county except Dade, where the concentration of Cuban and Haitian immigrants is by far the strongest.

Average household size in 1985 was largest in Gadsden and Baker counties, with 3.15 and 3.11, respectively. It was smallest in Pinellas (2.19), Charlotte (2.20) and Sarasota (2.21). As a general rule, average household size tends to be higher for black than white households, for rural than urban households and for younger than older persons. Although there is not a perfect correlation, the counties in Florida with large average household sizes tend to be rural and have a relatively high proportion of black households, while counties with small average household sizes tend to be urban and have a relatively high proportion of older persons.

People are fascinated by the future. Palm readers, astrologers and crystal ball gazers down through the centuries have found eager buyers for their predictions. Modern-day researchers and forecasters, using computers and large-scale models, continue to find willing audiences. There is particularly great interest in population projections, and for good reason: many types of public and private planning--for schools, hospitals, stores, houses, service stations, roads and countless other projects--require some information on future population trends. Yet the future is essentially unknowable. No matter how scientific and sophisticated our projection techniques, we cannot perfectly predict future population trends. In spite of years of developing high-quality data, statistical techniques and computer programs, we still cannot "see" into the future.

We are not completely lost, of course. We can observe population trends that have occurred in the past. We can collect data and build models based on historical trends and relationships. We can then make projections from these models showing what would happen if past trends continued or varied in some particular way. Since the future is intimately tied to the past, these projections will often provide reasonably accurate forecasts of future population change. If constructed and interpreted properly, population projections--although certainly not perfect predictions of the future--can be extremely useful tools for planning and policy analysis.

The projections published in this bulletin are for the permanent resident population of Florida; they do not include tourists or part-time/seasonal residents. Since the future cannot be predicted with absolute certainty, we have produced three sets of projections: low, medium and high. We believe the medium projection is generally more likely to provide an accurate forecast of future population change than either the low or high projections. The low and high projections, however, provide an indication of the range in which the future population might lie. While these projections provide useful benchmarks for planning and policy analysis, they should not be interpreted as the only possible scenarios for future population change. Other sources of information at the local level should be considered when using the projections for planning purposes (particularly for small counties).

State projections

State-level projections were made using a cohort-component methodology in which births, deaths and migration were projected separately for each age-sex cohort in the population. The base was the April 1, 1980 population of Florida as enumerated in the decennial census. Survival rates were applied to each age-sex cohort to project future mortality. These rates were based on Florida Life Tables for 1980 prepared by the Public Health Statistics Section of the Florida

Population Studies

Population Program · Bureau of Economic and Business Research · University of Florida

April, 1986 Bulletin No. 76

Department of Health and Rehabilitative Services. The survival rates were adjusted upward in 1990, 2000 and 2010 to account for projected increases in life expectancy (U.S. Census Bureau, *Current Population Reports*, Series P-25, No. 601, October 1975).

Migration rates were based on 1980 census data regarding migration behavior between 1975 and 1980. Inmigration rates were calculated by dividing 1975-1980 migration into Florida by the 1975 population of the United States (minus Florida) for each age-sex cohort. Outmigration rates were calculated by dividing 1975-1980 migration out of Florida by the 1975 Florida population for each age-sex cohort. Projections of inmigration were then made by applying inmigration rates to the population of the United States (minus Florida), and projections of outmigration made by applying outmigration rates to the Florida population. The projections of the United States population were taken from *Current Population Reports*, Series P-25, No. 952, May 1984.

Projections were made in five-year intervals, with each projection serving as the base for the following projection. Projected inmigration for each five-year interval was added to the survived Florida population at the end of that interval, and projected outmigration was subtracted, giving a projection of the population age five and older. Births and net migration of children less than age five were projected by applying age-specific birth rates (adjusted for child mortality) to the projected female population. These birth rates were based on Florida birth data between 1980 and 1984, and imply a total fertility rate of 1.9 births per woman. The 1985 projection was adjusted to be consistent with the 1985 total population estimate.

Three different migration assumptions were used, providing three sets of projections. The low series applied a weight of 0.9 to the inmigration rates for each age-sex cohort. This series implies net inmigration (i.e. the excess of inmigrants over outmigrants) of 150,000 to 200,000 per year, about the same as during the low-growth years of the 1970s and 1980s. The medium series applied a weight of 1.1 to the inmigration rates, yielding net inmigration numbers of 230,000 to 260,000 per year, about the average for Florida during the 1970s and 1980s. The high series applied the weight of 1.3 to the inmigration rates, yielding net migration numbers of 300,000 to 340,000 per year, about the same as during the high-growth years of the 1970s and 1980s. We believe the medium series is most likely to produce accurate forecasts of the Florida population.

County projections

While the cohort-component technique is a good way to make projections at the state level, it is not necessarily the best way to make projections at the county level. Many counties in Florida are so small that the number of persons in each age-sex category is inadequate for reliable cohort-component projections. Furthermore, county growth patterns are so volatile that a single technique based on the 1970-1980 time period may provide misleading results. We believe more useful projections can be made if a number of different techniques and historical time periods are used.

For counties we made eleven projections, using six different techniques and three different time periods. The starting point for each projection was the 1985 population estimate published by the Bureau of Economic and Business Research. Two projections were made using linear extrapolation, one using a base period of 1975-1985 and one using 1980-1985. One projection was based on the linear regression of population on time, using annual data from 1970 to 1985. One projection was based on the linear regression of population on time and time squared, using annual data from 1970 to 1985. Two projections were made by extrapolating exponential growth rates, one using a base period of 1975-1985 and the other 1980-1985. Three projections were made using a share-of-growth technique in which it was assumed that each county's share of the state's future population growth would be the same as it was during the base periods of 1970-1985, 1975-1985 and 1980-1985. Two projections were made using a shift-share technique in which it was assumed that each county's share of state population would change annually by the same linear amount as the average annual change during the base periods of 1975-1985 and 1980-1985.

These techniques provided eleven different sets of projections for each county. For 1990 the medium projection was based on the average of these eleven projections. For 1995, the medium projection was made by excluding the highest and lowest projections (thereby excluding techniques that tend to "explode" upward or downward when carried too far into the future) and taking the average of the nine remaining projections. For 2000, the medium projection excluded the two highest and two lowest projections, and used an average of the seven remaining projections. For 2005, the medium projection excluded the three highest and three lowest projections, and used an average of the five remaining projections. Our research has shown that taking the average of a number of different projections reduces the chances of making large errors and leads to more reliable projections. For the years 2010 to 2020 we held each county's share of state population at the same level as 2005. We believe that the continued extrapolation of past trends this far into the future is likely to be counterproductive. Some counties will grow more rapidly than the state as a whole, while others will grow more slowly. Unfortunately there is no way to know in advance which counties will fall into which of these two categories. Consequently we take a middle-of-the-road approach and hold shares constant.

In a number of counties we made special adjustments to the population before applying the techniques described above. This was done to account for such special populations as university students, military personnel and prison inmates. Adjustments were made for counties in which these special populations account for a large proportion of total population or where the special populations have moved counter to trends for the rest of the population. In the present set of projections adjustments were made for Alachua, Baker, Bradford, Brevard, Dade, Duval, Escambia, Gadsden, Jackson, Lafayette, Monroe, Leon, Okaloosa, Santa Rosa and Union counties.

The techniques described above were used to make the medium set of population projections. This is the set we believe is generally most likely to provide an accurate forecast

of future population. In all cases medium county projections were controlled to add to the state medium projection. We have also made a low and high set of projections to provide an indication of the potential variation around the medium projection. The low and high projections were based on an anlaysis of the errors observed when the projection techniques were applied to historic data. Although the analysis is still preliminary, we believe there is roughly a two-thirds probability that future populations will fall between the low and high projections.

Note: For the medium series, the sum of the county projections equals the state projection for each year (except for slight differences due to rounding). For the high and low series, however, the sum of the county projections does not equal the state projections. This occurs because potential variation around the medium projection is much greater for counties (especially small counties) than for the state as a whole.

Population estimates and projections by age and sex: Florida and its counties, 1985-2000

by
Stanley K. Smith
Population Program Director
and
Bashir Ahmed
Associate in Research

Bureau of Economic and Business Research
University of Florida

State level

Estimates of the 1985 Florida population by age and sex, and projections for the years 1990, 1995 and 2000, were made using a cohort-component methodology in which births, deaths and migration were projected separately for each age-sex cohort in the population. The starting point was the April 1, 1980 population as enumerated in the decennial census. Five-year survival rates were applied to each age-sex cohort to project the proportion surviving to 1985. These rates were based on Florida life tables for 1980, prepared by the Public Health Statistics Section of the Florida Department of Health and Rehabilitative Services. The survival rates were adjusted upward for the 1995 and 2000 projections to account for projected increases in life expectancy (U.S. Bureau of the Census, *Current Population Reports*, Series P-25, No. 601, October 1975).

Migration rates were based on 1980 census data regarding migration behavior between 1975 and 1980. Inmigration rates were calculated by dividing 1975-1980 migration into Florida by the 1975 population of the United States (minus Florida), for each age-sex cohort. Outmigration rates were calculated by dividing 1975-1980 migration out of Florida by the 1975 Florida population, for each age-sex cohort. Projections of inmigration were then made by applying the inmigration rates to the population of the United States (minus Florida) by age and sex, and projections of outmigration were made by applying the outmigration rates to the Florida population by age and sex. The projections of the United States population were taken from *Current Population Reports*, Series P-25, No. 952, May 1984.

Projections were made in five-year intervals, with each projected population serving as the base for the following projection. Projected inmigration for each five-year interval was added to the survived Florida population at the end of that interval and projected outmigration was subtracted, giving a projection of the population age 5 and older. Births and net migration of children less than age 5 were projected by applying age-specific birth rates (adjusted for child mortality) to the projected female population. These birth rates were based on Florida birth data for 1984 and imply a total fertility rate of 1.9 births per woman. The population less than age 5 was divided into males and females according to historic data: 51 percent male and 49 percent female.

The 1985 projection of total population was controlled to the 1985 population estimate published earlier this year (Bureau of Economic and Business Research, *Florida Estimates of Population: April 1, 1985*, University of Florida, February 1986). The population age 0-4 in 1985 was based directly on the number of births in Florida between 1980 and 1984. Consequently, the numbers shown for 1985 may be more properly interpreted as "estimates" rather than "projections."

In Florida, approximately 90 percent of population growth is due to net migration and only 10 percent is due to the excess of

births over deaths. The assumptions regarding future migration are therefore the most critical in projections of Florida population. We have used three different migration assumptions, yielding three series of population projections. In the low series, a weight of 0.9 was applied to the migration rates for each age-sex cohort. This series projects net inmigration (i.e. the excess of inmigrants over outmigrants) of 150,000-160,000 per year between 1985 and 2000, about the same as the low-growth years of the 1970s. The medium series was based on a weight of 1.1, yielding net migration inflows of 230,000-240,000 per year, about the average for Florida during the 1970s and first half of the 1980s. The high series was based on a weight of 1.3, yielding net migration inflows of 300,000-330,000 per year, about the same as the high-growth years of the 1970s and 1980s. The numbers published in this bulletin were taken from the medium series, which we believe is most likely to provide accurate forecasts of Florida's future population.

County level

County projections were made in a manner very similar to that used for the state projections. Survival rates and outmigration rates were applied to each age-sex cohort to project the number surviving and moving out; inmigration rates were applied to each age-sex cohort in the United States population to project the number moving in; and age-specific birth rates were applied to the female population to project the number of births and net migration of children less than age 5.

The in- and outmigration rates were based on in- and outmigration between 1975 and 1980 for each county, using a weight of 1.1 for inmigration rates and the same procedures described above for the state projections. Survival rates were based on Florida life tables for 1980, but for each county the survival rates were weighted averages of the state-level rates for whites and nonwhites. The weights were based on each county's proportion of white and nonwhite population in 1980. Thus the survival rates were somewhat different for each county, with the differences being determined by each county's racial structure. Similarly, county birth rates were weighted averages of state-level birth rates for whites and nonwhites, with the weights again determined by the 1980 proportion of whites and nonwhites in the county's population. The resulting total fertility rates ranged from 1.74 for Pasco County to 2.29 for Gadsden County.

In a number of counties, institutions account for a substantial proportion of total population. If the institutional population is following a different growth trend than the noninstitutional population in these counties, adjustments must be made before the usual projection techniques can be applied. In the present set of projections, adjustments for institutional populations were made for Alachua, Baker, Bradford, Gadsden, Leon, Monroe and Union counties. In these counties, the birth, death and migration rates were applied only to the noninstitutional population, and independent projections of the institutional population were added as a final step.

In all counties, the population projections by age and sex have been controlled to the medium series from the projections of total population published earlier this year (Bureau of Economic and Business Research, *Population Studies*, Bulletin No. 76, April 1986). The 1985 projection was controlled to the 1985 estimate of total population, so the numbers shown for 1985 may be interpreted as "estimates" rather than "projections."

Note: This bulletin provides projections only for the condensed age groups of 0-14, 15-24, 25-44, 45-64, 65+ and 18+. Complete projections of the population by five-year age groups up to age 85+ are available. Please contact the Bureau of Economic and Business Research for further information.

Estimates and projections of the black population by age and sex: Florida and its counties, 1985-2000

by
Stanley K. Smith
Population Program Director
and
Bashir Ahmed
Associate in Research

Bureau of Economic and Business Research
University of Florida

The 1980 Census counted more than 1,343,000 black persons as permanent residents of the State of Florida. This was an increase of 28.9 percent over the 1,042,000 counted in 1970. We estimate that by 1985 the number of blacks in Florida had increased another 14.4 percent, to 1,536,000. This bulletin presents estimates for 1985 and projections for 1990, 1995 and 2000 of the black population, by age and sex, for Florida and each of its counties.

The classification of persons as "black" reflects the self-identification of respondents in the 1970 and 1980 censuses. It does not denote any clear-cut scientific definition of biological stock. It includes all persons who indicated their race as black or negro, as well as persons who did not classify themselves in one of the specific race categories listed on the questionnaire, but reported entries such as Haitian, Nigerian or West Indian. The estimates and projections shown in this bulletin are based on the racial classifications used in the 1980 census.

State level

Estimates of the 1985 black population by age and sex, and projections for the years 1990, 1995 and 2000, were made using a cohort-component methodology in which births, deaths and migration were projected separately for each age-sex cohort in the black population. The starting point was the April 1, 1980 population as enumerated in the decennial census. Five-year survival rates were applied to each age-sex cohort to project the proportion surviving to 1985. These rates were based on Florida life tables for 1980, prepared by the Public Health Statistics Section of the Florida Department of Health and Rehabilitative Services. The survival rates were adjusted upward for the 1995 and 2000 projections to account for projected increases in life expectancy (U.S. Bureau of the Census, *Current Population Reports*, Series P-25, No. 601, October 1975).

Migration rates were based on 1980 census data regarding migration behavior between 1975 and 1980. Inmigration rates were calculated by dividing 1975-1980 migration of blacks into Florida by the 1975 black population of the United States (minus Florida), for each age-sex cohort. Outmigration rates were calculated by dividing the 1975-1980 migration of blacks out of Florida by the 1975 black population of Florida, for each age-sex cohort. Projections of inmigration were then made by applying the inmigration rates to the black population of the United States (minus Florida) by age and sex; these rates were weighted by 1.1 to account for the more rapid growth in Florida between 1980 and 1985 than between 1975 and 1980. Projections of outmigration were made by applying the outmigration rates to the black

population of Florida, by age and sex. The projections of the black population of the United States were taken from *Current Population Reports*, Series P-25, No. 952, May 1984.

Projections were made in five-year intervals, with each projected population serving as the base for the following projection. Projected inmigration for each five-year interval was added to the survived Florida population at the end of that interval and projected outmigration was subtracted, giving a projection of the black population age 5 and older. Births and net migration of children less than age 5 were projected by applying age-specific birth rates (adjusted for child mortality) to the projected black female population, by age. These birth rates were based on Florida birth data for nonwhites in 1984 and imply a total fertility rate of 2.7 births per woman. The population age 0-4 was divided into 51 percent male and 49 percent female based on historical data. For 1985, the population age 0-4 was adjusted to fit with the number of nonwhite births in Florida between 1980 and 1984.

County level

County projections of the black population were made in a manner very similar to that used for the state projections. Survival rates were based on state-level mortality data and were applied to each age-sex cohort to project the number surviving to the end of each five-year projection interval. In- and outmigration rates were based on migration into and out of the county between 1975 and 1980. Inmigration rates were applied to each age-sex cohort of the black population of the United States to project the number of blacks moving into the county; and outmigration rates were applied to each age-sex cohort of the county's black population to project the number moving out. The number of births and net migration of children less than age 5 were projected by applying state-level age-specific birth rates to the female population of each county. (For 1985 the population 0-4 was adjusted to fit with the number of nonwhite births in the county between 1980 and 1984.)

In a number of counties, institutions account for a substantial proportion of the black population. If the institutional population is following a different growth trend than the noninstitutional population in these counties, adjustments must be made before the usual projection techniques can be applied. In the present set of projections, adjustments for institutional black populations were made for Alachua, Baker, Bradford, Gadsden, Leon, Monroe and Union counties. In these counties, the birth, death and migration rates were applied only to the noninstitutional black population, and independent projections of the institutional black population were added as a final step.

Note: This bulletin provides projections only for the condensed age groups of 0-14, 15-24, 25-44, 45-64, 65+ and 18+. Complete projections of the black population by five-year age groups up to age 85+ are available. Please contact the Bureau of Economic and Business Research for further information.
